Key Components of MATLAB FEA Code

- Mesh Generation: Creating nodes and elements. - Material Property Definition: Specifying Young’s modulus, Poisson’s ratio, etc. - Element Stiffness Calculation: Computing elemental matrices. - Assembly Procedure: Building the global stiffness matrix. - Applying Boundary Conditions: Prescribing fixed or loaded nodes. - Solving the System: Computing displacements. - Post-processing: Calculating stresses and visualizing results. Below is a simplified outline of MATLAB code structure for a 2D elasticity problem. % Define material properties E = 210e9; % Young's modulus in Pascals nu = 0.3; % Poisson's ratio % Generate mesh (nodes and elements) [nodes, elements] = generateMesh(); % Initialize global stiffness matrix K = zeros(totalDofs, totalDofs); % Assemble global stiffness matrix for e = 1:size(elements,1) Ke = elementStiffness(nodes, elements(e,:), E, nu); K = assembleGlobalK(K, Ke, elements(e,:)); end % Apply boundary conditions [K_mod, F_mod] =

applyBoundaryConditions(K, F, boundaryConditions); % Solve for displacements displacements = K_mod \ F_mod; % Post-process results stress = computeStress(nodes, elements, displacements); % Visualize results visualizeDisplacements(nodes, elements, displacements); This skeleton provides a starting point for custom FEA implementation.

Implementing 2D Finite Element Analysis in MATLAB

2D analyses are often the first step in finite element modeling due to their relative simplicity and computational efficiency.

Common 2D Elements

- Triangular elements (T3, T6): Suitable for complex geometries. - Quadrilateral elements (Q4, Q8): Suitable for structured grids.

Sample MATLAB Code for Triangular Elements

Below is an example of calculating the stiffness matrix for a single triangular element. function Ke = elementStiffness(nodes, elementNodes, E, nu) % Extract node coordinates coords = nodes(elementNodes, :); x = coords(:,1); y = coords(:,2); % Compute area of the triangle A = polyarea(x, y); % B matrix calculation beta = [y(2) - y(3); y(3) - y(1); y(1) - y(2)]; gamma = [x(3) - x(2); x(1) - x(3); x(2) - x(1)]; B = (1/(2A)) [beta' ; gamma'] ; % Constitutive matrix D for plane stress D = (E / (1 - nu^2)) [1, nu, 0; nu, 1, 0; 0, 0, (1 - nu)/2]; % Element stiffness matrix Ke = A (B') D B; end This function computes the local stiffness matrix for a triangular element, which can be assembled into the global matrix.

Extending MATLAB FEA Codes to 3D Solid Analysis

While 2D analysis provides valuable insights, real-world problems often require 3D modeling.

3D Element Types

- Tetrahedral elements (TET4, TET10) - Hexahedral elements (C3D8, C3D20)

Key Considerations for 3D Implementation

- Managing more complex node connectivity. - Computing 3D shape functions and derivatives. - Handling larger stiffness matrices and boundary conditions. - Visualizing 3D stress and displacement fields.

Sample MATLAB Strategy for 3D Analysis

- Develop mesh generation routines for tetrahedral or hexahedral meshes. - Formulate element stiffness matrices using 3D shape functions. - Assemble the global stiffness matrix. - Apply boundary and loading conditions. - Solve for displacements and evaluate stresses. While 3D FEA coding is more complex, the principles mirror those in 2D with added geometric and computational complexity.

Boundary Conditions and Force Applications in MATLAB FEA

Applying boundary conditions correctly is crucial for obtaining meaningful results.

Types of Boundary Conditions

- Fixed supports: Zero displacements at certain nodes. - Prescribed displacements: Known displacement values. - Applied forces: External loads or pressures on nodes or surfaces.

Implementing Boundary Conditions in MATLAB

Typically involves modifying the global stiffness matrix and force vector: 1. Identify degrees of freedom (DOFs) to constrain. 2. Zero out corresponding rows and columns in the stiffness matrix. 3. Set diagonal entries to a large number or unity. 4. Adjust the force vector accordingly. function [K_mod, F_mod] = applyBoundaryConditions(K, F, boundaryConditions) for i = 1:length(boundaryConditions) dof = boundaryConditions(i).dof; value = boundaryConditions(i).value; K(dof, :) = 0; K(:, dof) = 0; K(dof, dof) = 1; F(dof) = value; end K_mod = K; F_mod = F; end

Post-Processing FEA Results in MATLAB

After solving the system, the next step is extracting useful information from the displacement solution.

Calculating Stresses and Strains

Using the displacement vector, strains are computed via strain-displacement matrices, then stresses are obtained through constitutive relations. function stress = computeStress(nodes, elements, displacements) stress = zeros(size(elements,1), 3); % For 2D plane stress for e = 1:size(elements,1) coords = nodes(elements(e,:), :); A = polyarea(coords(:,1), coords(:,2)); B = computeBMatrix(coords); strain = B displacements(elements(e,:) 2 - 1); % Adjust for DOF indexing stress(e,:) = D strain; end end Visualization tools such as `patch` or `quiver` can help display displacement and stress distributions.
